

Assignment

Server-side Database and Dynamic Control Creation

60 points

See Canvas for due date

Entity Relationship - Sales Transaction

This assignment simulates an actual sales report as might be found in an order-entry system. Server-side database processing will achieve fine-grained control of database information by approaching database access one table at a time.

Create a database in SQL Server that complies with the ERD above to represent sales transactions:

- Customer
- Invoice
- LineItem
- Inventory
- Supplier (not used in this exercise)

Populate the tables with proper referential data.

Create an ASP.NET web page that will present detail and summary sales information for each open order (An open order is one where the invoice status is 'Open'):

- Customer information (customer number, name, billing address, shipping address, etc.)
- Invoice information (invoice number, order date, status)
- Line item information with extended price and extended weight (SKU, description, quantity, unit price)

Summary information across all invoices:

- Order count
- Average order amount
- Total sales

Note: This application should be 'portfolio-worthy.'

Publish your application to your website. Send your .aspx and .cs source files as attachments and a link to your page to cpeters39@gmail.com.
